

**Example: A semi-infinite problem with constant heat flux**

A large block of steel  $k = 45 \text{ W/m} \cdot ^\circ\text{C}$ ,  $\alpha = 1.4 \times 10^{-5} \text{ m}^2/\text{s}$  is initially at uniform temperature of  $35^\circ\text{C}$ . The surface is exposed to a heat flux a) by suddenly raising the surface temperature to  $250^\circ\text{C}$  and b) through constant heat flux of  $3.2 \times 10^5 \text{ W/m}^2$ . Calculate the temperature at depth of  $2.5 \text{ cm}$  after  $30 \text{ s}$  for both these cases.

Case 1

$$\frac{x}{2\sqrt{\alpha t}} = \frac{0.025}{2\sqrt{1.4 \times 10^{-5} \times 30}} = 0.61$$

Table B.2  $\text{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right) = \text{erf}(0.61)$   
 $= 0.61164$

eq: 5.60  $\Rightarrow \frac{T(x,t) - T_s}{T_i - T_s} = \text{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right)$

$$\frac{T - 250}{35 - 250} = 0.61164 \Rightarrow T = 118.5^\circ\text{C}$$

Case 2 constant heat flux

eq: 5.62

$$T(x,t) - T_i = \frac{2q''(\alpha t)^{1/2}}{k} \exp\left(-\frac{x^2}{4\alpha t}\right) - \frac{q''x}{k} \left(1 - \text{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right)\right)$$

$$T_{(2.5\text{cm}, t=30\text{s})} = 79.3^\circ\text{C}$$
